

Ablation robustness of the 4,096-component decomposition — VPD §3.2

VPD's version of this plot is partly a FAITHFULNESS curve: its decomposition approximates the target's weights, needs a residual Δ -component, and reports CE 2.72–3.02 against a 2.71 target. Ours cannot be — the shares sum to exactly 1 per weight entry, so $K=0$ reproduces the model bit-for-bit and there is no reconstruction error to show. This is therefore a pure MINIMALITY curve. Note the curves rise far past uniform guessing: a model with its components removed is confidently wrong, not merely uninformed. Ablating a set is one elementwise mask per matrix, so all 90 points take 21 seconds.
