

Intruder detection — VPD Fig. 6, on the 4,096-component decomposition

A judge sees five text windows with one token marked in each: four where the component fires, and one intruder. It must say which does not belong. No label is shown, so this measures the decomposition rather than the labelling. The hard condition draws the intruder from the component's NEAREST NEIGHBOUR in centroid space (mean cosine 0.81) — near-chance accuracy there would mean C=4,096 had split one feature in two. It does not: adjacent components stay 89% distinguishable. Error bars are 95% Wilson intervals; claude-sonnet-5 as judge.

Components are coherent without their labels

The self-graded scale survives an outside test
